Unit Commitment and Dispatch with Coordination of Wind and Pumped Storage Hydro Units by using Cuckoo Search Algorithm

R.Jayashree[1]and R.Soundarapandian[2]

Abstract ---This paper proposes a multi objective model for Advanced Unit Commitment (AUC) with wind power and Pumped Storage (PS) units using Cuckoo Search (CS) algorithm. The novelty of the proposed method is improved levy flight searching ability, random reduction and ability to adapt complex optimization problems. Here, the CS algorithm to accommodate wind output uncertainty, with the multi-objective of providing an optimal AUC schedule for the thermal generators in the day-ahead market that minimizes the total cost under the different wind power output scenario. The proposed method is more reliable for AUC because it considering the wind power uncertainty using the Artificial Neural Network (ANN) and PS units, which are significantly reduces the total cost. Then the proposed method is implemented in the MATLAB/simulink platform and tested under IEEE standard bench mark system. The proposed method performance has been verified through the comparison analysis with the existing techniques. The comparison results were proved the superiority of the proposed method.

Key words: AUC, PS, CS, ANN, wind power

I. INTRODUCTION

Regarding to worldwide environmental change with discharges and consumption of fossil fuels, renewable energy sources are utilized in the power framework systems to overcome monetary, ecological, mechanical, and group level needs [1-2]. Between that, the wind energy era possesses acquired significant expense along with transform into probably the most develop green energy program to the conventional assets [3]. As the wind power entrances have expanded in the due course of the recent decade, more inventive and advanced methodologies are usually received in the present providing restriction planning, working conventions and methods because of its irregularity and unconventionality [4-5].Several procedures may be used to cater to wind electric power variability including innovative model dedication, along with controlling wind electric power variations together with pumped-storage hydro and superior supplementary program procurement.

The authors are with B.S. Abdur Rahman University, Chennai, India

To satisfy the need in cheaper cost, we've to make the optimization problem which determines which electric power plant life must be stimulated and/or banned on the regarded as period of time. It is termed because Unit Commitment optimization problem [6-7]. By employing, the lowest generation expense is achieved when each of the generation units together with wind electric power are usually devoted [8]. Regarding committing wind electric power from the electric power program operation, it an accurate predicting product which can figure out your behavior connected with wind in advance generally some day to consider booking selections [9-10]. As outlined by [11], the wind velocities variations are usually simulated through the distribution operate that is utilized by electric power program employees regarding identifying generation activities. For adhering the wind force throughout most exceedingly terrible situations, pumped-capacity hydro generation units are utilized to store the overabundance vitality and give the store and adaptability when required which expands the wind power dispatch ability [12-13]. Anyhow, it had regional and land constraints which makes it valuable just for a specific force framework region [14].

This paper focuses on a multi objective model for Advanced Unit Commitment (AUC) with wind power and Pumped Storage (PS) units using Cuckoo Search (CS) algorithm. The novelty of the proposed method is improved levy flight searching ability, random reduction and ability to adapt complex optimization problems. Here, the CS algorithm to accommodate wind output uncertainty, with the multi-objective of providing an optimal AUC schedule for the thermal generators in the day-ahead market that minimizes the total cost under the different wind power output scenario. The proposed method more reliable for AUC because it considering the wind power uncertainty using the Artificial Neural Network (ANN) and PS units, which are significantly reduces the total cost. The rest of the paper organized as follows: the problem formulation is explained in the section 2; the proposed algorithm brief explanation is explained in section 3; the suggested technique achievement results and the related discussions are given in section 4; and section 5 ends the paper.

II. PROBLEM FORMULATION OF AUC

The AUC problem consists of different kinds of costs such as thermal generating units optimal combinations fuel cost and start up costs of the thermal generating units. Here, the thermal generation is limited by using the probability of the wind power generation. The operational costs of PS units are assumed to be zero [15], so there is no need to consider the objective function. Therefore the selection of objective function should minimize the above mentioned cost functions, which is described in the following equation (1).

$$F_{TC} = \sum_{t=1}^{H}\sum_{i=1}^{N}\left[f_c(P_{TG}(i,t))U(i,t) + SC(i,t)\right] \times prob_{WT}(j,t) \tag{1}$$

Where, $f_c\left[P_{TG}(i,t)\right] = a_i + b_i P_{TG}(i,t) + c_i P_{TG}^2(i,t)$ (2)
(fuel cost in \$)

$$SC(i,t) = k_{o,i}\left[1 - \exp\left(\frac{T_{off}(i,t)}{k_{1,i}}\right)\right] + k_{2,i} \tag{3}$$

(Startup cost)

F_{TC} is the total cost; $f_c\left[P_{TG}(i,t)\right]$ is the fuel cost of the thermal generating units (\$); H is the total number of hours; $U(i,t)$ is the status of the unit i at t^{th} hour, i.e., 1 for ON and 0 for OFF; a_i, b_i and c_i are the fuel cost coefficients of the thermal generating unit i at t^{th} hour; $prob_{WT}(j,t)$ is the probability of the wind generator unit j at t^{th} hour, which is calculated based on wind power uncertainty; $P_{TG}(i,t)$ is the output power of the generator unit i at t^{th} hour; $SC(i,t)$ is the startup cost of unit i at t^{th} hour; N is the number of generating units; $k_{o,i}$, $k_{1,i}$ and $k_{2,i}$ are the startup cost coefficients of the thermal generating unit i and $T_{off}(i,t)$ is duration at which thermal generating unit i has been off at t^{th} hour. The generating unit's ON and OFF status was identified by using the proposed CS algorithm. The above mentioned fitness function is subjected to the following constraints.

A. System Constraints

The cost function of the AUC problem given by equation (1) is subjected to the following constraints.

(i). System Power balance constraint

The total power generated from the different types of sources like thermal generating unit, wind power generating unit and PS unit at each hour must be equal to the load of the corresponding hour. This constraint is explained in the following equation (4).

$$P_{TD}(t) = \sum_{i=1}^{n} P_{TG}(i,t)U(i,t) + P_{WT}^{NN}(j,t) + \sum_{l=1}^{n} P_{PS}(l,t)S(l,t) \tag{4}$$

Where, $P_{TD}(t)$ is the total demand at period t; $P_{TGi}(i,t)$ is the power generated from thermal unit i at hour t; $P_{WT}^{NN}(j,t)$ is the power generated from wind unit j at hour t, which is attained from the ANN; $P_{PS}(l,t)$ is the output power of the PS unit l at hour t. The power system spinning reserve constraint is explained in the following section.

(ii). Spinning reserve constraint

The system spinning reserve requirement is described in the following equation (5).

$$\sum_{i=1}^{n} P_{TG}^{\max}(i,t)U(i,t) + \sum_{l=1}^{n} P_{PS-g}^{\max}(l,t) + \sum_{l=1}^{n} P_{PS}(l,t)S(l,t) - P_{TD}(t) \geq R(t) \tag{5}$$

Where, $S(l,t) = -1,0,1$ represented the pumping, idle and generating mode of PS units respectively; is the maximum output power limit of the thermal unit $P_{PS-g}^{\max}(l,t)$ is the maximum generating power of PS l at hour t; $R(t)$ is the power system spinning reserve requirement at hour t. The subjected thermal units and PS units constraints are briefly described in the following.

B. Thermal unit's constraints

The thermal generating system consists of different types of constraints such as generation capacity, uptime and down time of the generators and ramp generation, which are described as follow.

(i). Generating capacity constraints [16]

$$P_{TG}^{\min}(i,t) \leq P_{TG}(i,t) \leq P_{TG}^{\max}(i,t) \tag{6}$$

(ii). Minimum up time limit [16]

$$T_{on}(i,t) > Min\,up(t) \tag{7}$$

(iii). Minimum down time [16]

$$T_{off}(i,t) > Min\,down(t) \tag{8}$$

(iv). Ramp generation [16]

$$P_{TG}(i,t) - P_{TG}(i,t-1) \leq RU(i) \tag{9}$$

as generation increases

$$P_{TG}(i,t) - P_{TG}(i,t-1) \leq RD(i) \tag{10}$$

as generation increases

Where, $P_{TG}^{\min}(i,t)$ and $P_{TG}^{\max}(i,t)$ are the minimum and maximum power of thermal generating unit i at t^{th} hour; $Min\,up(t)$ is the minimum up time of thermal generating unit at t^{th} hour; $Min\,down(t)$ is the minimum down time of thermal generating unit at t^{th} hour; $T_{on}(i,t)$ is duration at which thermal generating unit i has been on at t^{th} hour; $RU(i)$ and $RD(i)$ are the ramp up and down limit of the unit i. The PS unit constraints are described in the following section 2.3.

C. PS unit's constraints

The PS unit contains the generating capacity constraints, water flow constraints and reservoir constraints, which are described as follow.

(i).Generating capacity constraints [16]

$$P_{PS-g}^{\min}(l) \leq P_{PS-g}(l,t) \leq P_{PS-g}^{\max}(l) \tag{11}$$

$$P_{PS-p}^{\min}(l) \leq P_{PS-p}(l,t) \leq P_{PS-p}^{\max}(l) \tag{12}$$

(ii).Water flow constraints [22]

$$Q_{g}^{\min}(l) \leq Q_{g}(l,t) \leq Q_{g}^{\max}(l) \tag{13}$$

$$Q_{p}^{\min}(l) \leq Q_{p}(l,t) \leq Q_{p}^{\max}(l) \tag{14}$$

(iii).Upper and lower limits of the reservoir [16]

$$V_{up}^{\min}(l) \leq V_{up}(l,t) \leq V_{up}^{\max}(l) \tag{15}$$

$$V_{low}^{\min}(l) \leq V_{low}(l,t) \leq V_{low}^{\max}(l) \tag{16}$$

(iv).Water balance between upper and lower reservoir [16]

$$V_{up}(l,t+1) = V_{up}(l,t) \mp \left|Q_{g(p)}(l,t)\right| S(l,t) \tag{17}$$

$$V_{low}(l,t+1) = V_{up}(l,t) \pm \left|Q_{g(p)}(l,t)\right| S(l,t) \tag{18}$$

Where the initial conditions of the upper and lower reservoirs are

$$V_{up}(l,0) = V_{up}^{0}(l) \tag{19}$$

$$V_{low}(l,0) = V_{low}^{0}(l) \tag{20}$$

Where, $P_{PS-g}^{\min}(l)$ and $P_{PS-g}^{\max}(l)$ are the minimum, maximum generating power of PS unit l; $P_{PS-p}^{\min}(l)$ and $P_{PS-p}^{\max}(l)$ are the minimum, maximum pumping power of PS unit; $Q_{g}^{\min}(l)$ and $Q_{g}^{\max}(l)$ are the minimum, maximum water discharge of PS unit l at generating mode; $Q_{p}^{\min}(l)$ and $Q_{p}^{\max}(l)$ are the minimum, maximum water discharge of PS unit l at pumping mode; $V_{up}^{\min}(l)$ and $V_{up}^{\max}(l)$ are the minimum, maximum volume of upper reservoir of PS unit l; $V_{low}^{\min}(l)$ and $V_{low}^{\max}(l)$ are the minimum, maximum volume of lower reservoir of PS unit l; $V_{up}^{0}(l)$ and $V_{low}^{0}(l)$ is upper and lower reservoir initial volume of PS unit l. The output power of the PS unit has been modeled by the following equation (21).

$$P_{PS}(l,t) = C_{l,1}Q^2(l,t) + C_{l,2}V^2(l,t) + C_{l,3}Q(l,t)V(l,t) + C_{l,4}Q(l,t) + C_{l,5}V(l,t) + C_{l,6} \tag{21}$$

Where, $P_{PS}(l,t)$ is the output power of the PS unit l at t^{th} hour; $C_{l,1} \ldots C_{l,6}$ is the power coefficients of the PS units; $Q(l,t)$ is the water discharging of PS unit l at t^{th} hour; $V(l,t)$ is the voltage of reservoir of PS unit l at t^{th} hour.

The wind power generation, which depends on the wind power uncertainty, is attained from the ANN, which is briefly described in the following section 2.4.

D. Wind power generation prediction using ANN

The neural network is one of the artificial intelligence (AI) techniques [17] which workings are based on the training and testing process. It is a machine learning approach that models a human brain and consists of a number of artificial neurons. The presented neurons have the interior connections and each neuron in ANN receives a number of inputs, depending on the activation functions of the ANN results in the output level of the neuron. Here the wind power generation $P_{WT}^{NN}(j,t)$ can be identified by the ANN technique. By using the target with corresponding inputs, the ANN becomes trained using the back propagation algorithm. During the testing time the resultant wind power generation can be obtained. The back propagation algorithm training steps are explained below.

Back propagation learning algorithm steps:

Step 1: Initialization of the input layer, hidden layer and output layer weights of the neural network, i.e., day (D), hour (H), wind speed $S_{WT}(j,t)$ and wind power generation $P_{WT}(j,t)$.

Step 2: Learning the network according to the input and the corresponding target.

Step 3: Calculate the back propagation error of the target $P_{WT}(j,t)_1, P_{WT}(j,t)_2$ *and* $P_{WT}(j,t)_k$.

$$\left.\begin{aligned} BP_{error}^1 &= P_{WT}(j,t)_1^{NN(tar)} - P_{WT}(j,t)_1^{NN(out)} \\ BP_{error}^2 &= P_{WT}(j,t)_2^{NN(tar)} - P_{WT}(j,t)_2^{NN(out)} \\ BP_{error}^k &= P_{WT}(j,t)_k^{NN(tar)} - P_{WT}(j,t)_k^{NN(out)} \end{aligned}\right\} \quad (22)$$

Where, $P_{WT}(j,t)_k^{NN(tar)}$ is the network target of the k^{th} node and $P_{WT}(j,t)_k^{NN(out)}$ is the current output of the network.

Step 4: The current output of the network is determined by following them,

$$\left.\begin{aligned} P_{WT}(j,t)_1^{NN(out)} &= \alpha_1 + \sum_{n=1}^{N} w_{1n}\, P_{WT}(j,t)_1^{NN}(n) \\ P_{WT}(j,t)_2^{NN(out)} &= \alpha_2 + \sum_{n=1}^{N} w_{2n}\, P_{WT}(j,t)_2^{NN}(n) \\ P_{WT}(j,t)_k^{NN(out)} &= \alpha_k + \sum_{n=1}^{N} w_{kn}\, P_{WT}(j,t)_k^{NN}(n) \end{aligned}\right\} \quad (23)$$

Where, α_1, α_2 and α_k are the bias function of the node $1, 2$ *and* k respectively.

$$\left.\begin{aligned} P_{WT}(j,t)_1^{NN}(n) &= \frac{1}{1+\exp(-w_{1n}P_{WT}(j,t)_1 - w_{2n}P_{WT}(j,t)_2)} \\ P_{WT}(j,t)_2^{NN}(n) &= \frac{1}{1+\exp(-w_{2n}P_{WT}(j,t)_2 - w_{kn}P_{WT}(j,t)_k)} \\ P_{WT}(j,t)_k^{NN}(n) &= \frac{1}{1+\exp(-w_{kn}P_{WT}(j,t)_k - w_{1n}P_{WT}(j,t)_1)} \end{aligned}\right\} \quad (24)$$

Step 5: The new weights of the each neurons of the network are updated by $w_{new} = w_{old} + \Delta w$. Here, w_{new} is the new weight, w_{old} is the previous weight and Δw is the change of weight of each output. The change of weight is determined as follows:

$$\left.\begin{aligned} \Delta w_1 &= \delta . P_{WT}(j,t)_1 . BP_{error}^1 \\ \Delta w_2 &= \delta . P_{WT}(j,t)_2 . BP_{error}^2 \\ \Delta w_k &= \delta . P_{WT}(j,t)_k . BP_{error}^k \end{aligned}\right\} \quad (25)$$

Where, δ is the learning rate (0.2 to 0.5).

Step 6: Repeat the above steps till the BP_{error} gets minimized $BP_{error} < 0.1$.

Once the neural network training process is completed, the network is trained well for the identifying $P_{WT}^{NN}(j,t)$. Based on the output of the network, the CS algorithm has been performing the AUC. The CS algorithm based optimum combination of generator units selection is depending on the load demand, which is explained in the following section 4.

III. CS ALGORITHM BASED OPTIMUM GENERATION UNIT COMBINATION SELECTION

The proposed method AUC problem has been solved by optimizing the generator combination using CS algorithm according to the load demand. Here, the wind power is selected according to the uncertainty of the wind characteristics, i.e., from the neural network, which should minimize the generating capacity of the generators. The attained optimal combinations of generating units are used to minimize the fuel cost and the startup cost of the generating units. The step by step process for optimizing the combination of generator unit is explained in the following subsection.

Algorithm

Step1: Initialize the input host nest and cuckoo parameters such as thermal generators generation limits, wind power generation limit from the ANN and the PS unit generation limits.

Step 2: Generate the random population of n host nests using the following equation (26).

$$X_i = [X_1, X_2 \ldots X_n] \tag{26}$$

Step 3: Set the iteration count k=1.

Step 4: Determine the fitness of the nests by means of the fitness equation (1).

Step 5: Determine the maximum and minimum fitness of the initial population. From the population minimum values are stored for the best solutions.

Step 6: Generate the new solution X_i^{t+1} for cuckoo i using levy flight, which can be represented as follows

$$X_i^{t+1} = X_i^t + \alpha \oplus Levy(\lambda) \tag{27}$$

Where, $\alpha > 0$ is the step size, which should be related to the scale of the problem of interest and the product $\oplus$ means entry-wise multiplications. In this work, we consider Levy flight in which the step-lengths are distributed according to the following probability distribution

$$Levy(\lambda) = t^{-\lambda}, 1 < \lambda \leq 3 \tag{28}$$

Step 7: Discover the worst nests based on the probability (p_a) and substitute the worst nests by new set of solutions.

Step 8: Test the termination criteria. Go to step 9 if it is met, if not go to step 3.

Step 9: Terminate the process.

Once the process is completed the network is ready to give the better generator units combination for different types of load demand. The structure of the proposed method for optimizing the optimal generating unit is described in figure 2. The proposed technique is tested in the MATLAB/simulink platform and the results are analyzed in Section 5.

IV. COMPUTATIONAL RESULTS AND DISCUSSION

In this section, we presented the numerical experiments of the proposed algorithm in MATLAB/Simulink 7.10.0 (R2012a) platform, 4GB RAM and Intel(R) core(TM) i5 with IEEE 118 standard bench mark system. There are 54 generating units in the system. In [18], the detailed system data and load profile for IEEE 118-bus system are found. The same as in [18], the spinning reserve of the system is fixed based on the proceeding events of the system. The effectiveness of the proposed method is verified by comparing with the conventional GA technique. The implementation parameters for wind power plant and PS unit are described in the table 1.

Table.1: Implementation parameters

Sources	Parameters	Values
Wind turbine	Minimum and maximum wind speed	3 m/s to 12.25m/s
	Minimum and maximum wind power	500MW to 2000MW
PS unit	Total number of units	4
	Minimum and maximum generating power	10MW to 100MW
	Minimum and maximum absorbing power	20MW to 110MW
	Minimum and maximum water level at generation	3.5MCFT to 4 MCFT
	Minimum and maximum water level at absorption	2.8MCFT to 3 MCFT

Based on the wind power variation and the load demand value, the AUC has been performed by using the proposed CS method. The historical wind speed (m/s) and corresponding wind power generation (MW) data for 24 hours are utilized for training the ANN. From the ANN output, the wind uncertainty probability has been calculated. The ANN based wind power prediction for 24 hours are tabulated in the following table 2.

Table.2: Wind power probability for 24 hours

Hour	Wind speed	Wind power	Wind
1	9.0243	254.2986	0.9395
2	8.8272	119.4453	0.9951
3	3.0430	744.3672	0.7861

24	8.0980	1959.8248	0.6017

The wind power variation has been attained from the ANN technique. Here, the hourly based wind speed is given as the input and found the wind power probability. The ANN technique efficient training and testing process helps to identify the optimal wind probability. From the table.2, we can understand that the wind speed variation at the different time intervals. By using the wind power probability, the generator unit's configurations have been selected. Any peak load conditions may occur in the bus system, the load curtailment has been reduced using the allocation of the PS units. The PS units power production and the unit commitment has been described in the table 3. Here, the ON/OFF status of the PS units during the AUC condition is explained. In the table 3, the PS unit power generation is varied from 96 MW to 235 MW during the required load demand. The wind power generation and PS unit's power generations are mostly exploited to decrease the usage of thermal generator units.

Table.3: PS unit status with generated power

Hour	Unit 1 to 4	Generated power (MW)
1	1011	200.4766
2	1010	144.7205
3	1010	145.1663
4	1010	126.6755
5	1010	135.5367
6	1010	96.5397
7	1011	163.6424
8	1011	157.1692
9	1011	195.1307

18	1111	174.6286
19	1111	194.7727
20	1111	230.5265
21	1111	227.3319
22	1111	234.9681
23	1111	194.4548
24	1011	181.543

The IEEE 118 bus system 54 generators unit status with operating cost during the 24 hours load demand is illustrated in the table 4.From the mentioned operating cost, the initial hour occupies the maximum operating cost such as 31134.6692$. It has been reduced at the 15th hour 6162.1347$. Finally the total operating cost of the total period has been calculated, which is clearly shown that the proposed AUC satisfies the reported load demand at 521778.4$ total operating cost. In the table 4, at each and every hour the operating cost of the thermal generators units are noticed. Then the thermal generator units dispatch the amount for every hour has been noticed in the table 5, which also have the startup cost of the units.

Table.4: Thermal generator unit status

Hour	Unit no 1 to 54	Operating cost ($)
1	111001111001111111111111110011111111111111111111111111	31134.6692

Total operating cost		521778.4

The effectiveness of the proposed method is compared with the different techniques such as SDP [18], ABC-LR [19], BRCFF [20] and GA in the table 8. Here, the SDP, ABC-LR and BRCFF are normal unit commitment techniques, i.e., not considers the wind power generation and PS unit power generation. The SDP has 1645445.00$ total operating cost of the thermal generator units. The ABC-LR and BRCFF consists of 1644269.70$ and 1644141.00$ total operating cost respectively. The GA technique involves in the AUC, which has the total operating cost of the generator units is 742256.81$. The proposed method has minimum total operating cost 521778.4$ compared to the other techniques. Because it effectively utilizes the renewable energy sources of power generation during the peak load conditions. According to the availability of the renewable energy power generation the thermal generator units are allowed for generation. So the startup costs and fuel costs are effectively reduced. Table 5 shows the thermal generator units dispatch for every hour and also the startup cost of the units which satisfies the load demand every hour.

Table.5: Thermal generators dispatch

The figure.1 shows the load demand of the system for 24 hours. It was clearly shown that the peak load demand of the system is 6000 MW. Here, the load demand has been varied between the 3400 MW to 6000 MW. According to the load demand variation, the AUC has been performed.

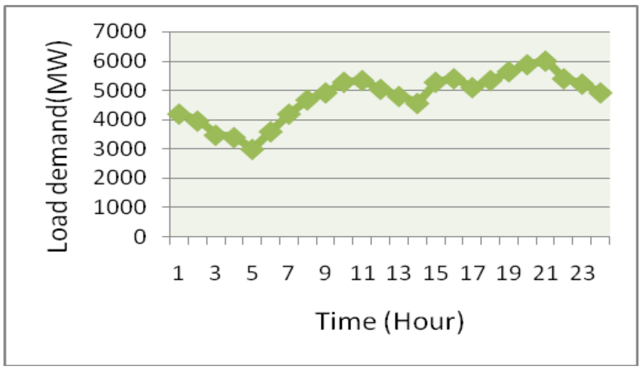

Figure.1: Load Demand Curve

The listed load demand is solved by the proposed AUC technique. By using the wind power generation and PS unit's power, the fuel cost and startup cost of the thermal generators are reduced. The IEEE 118 bus systems with 54 generator units using different techniques are compared in the figure 2. It was clearly shown that the proposed method have reduced the operating cost compared to the other techniques.

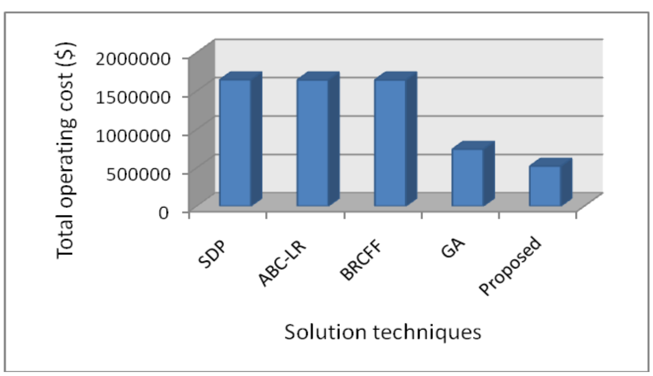

Figure.2: Performance comparison of different techniques

VI. Conclusion

This paper discussed about the proposed innovative approach for Advanced Unit Commitment (AUC) with wind power and Pumped Storage (PS) units. In the proposed method mainly schedule the AUC of the thermal generators units for a day-ahead market by considering the wind power uncertainty and PS units. The attained AUC schedule considers the wind uncertainty from the ANN technique and PS units, which significantly minimizes the total cost of the system. The advantage of the proposed method is effective, more reliable and feasible for complex problems. The proposed technique tested under IEEE 118 standard bench mark system with 54 generator units and the numerical results were compared with the Genetic Algorithm (GA). The comparison analysis shows that the proposed method effectively minimizes the total cost while comparing with the GA technique.

R. Jayashree is working as a professor in B.S. Abdur Rahman University, Chennai, India. She has twenty one years of teaching and Eight years of research experience. She has received M.E degree in Power System Engineering from Anna University, Chennai in the year of 1992. She obtained Ph.D degree in Electrical Engineering from Anna University in the year of 2008.Additionally she has been leading several research projects related with the integration of renewable generation and DG in the power system.

R. Soundarapandian has done B.E/EEE in the year 2009 and M.E/Power Systems Engineering in the year 2011. He has Five years of teaching experience. He is pursuing his research in the area of power system optimization in the Department of EEE at B.S. Abdur Rahman University, Chennai. Currently, He is working as an Assistant Professor in the Department of Ocean Engineering at VELS University, Chennai. In 2015, he joined the staff of VELS University as a Researcher, and is now Coordinator of the Marine Electricals and Offshore Power Systems Unit. He is a life member of Indian Society for Technical Education. His areas of interest are Power System Analysis and power system stability and control.
