

# A software for calculation of optimum conditions for cotton, viscose, polyester and wool based yarn bobbins in a hot-air bobbin dryer

H. Kuşçu, K. Kahveci, U. Akyol and A. Cihan

**Abstract**—In this study, a software has been developed to predict the optimum drying conditions of viscose, wool, polyester and cotton based yarn bobbins for drying in a pressurized hot air dryer. For this purpose, firstly, a suitable drying model has been found in defining the drying behavior of bobbins using the experimental drying behavior. After that, additional regression analyses have been made to take into account the effect of the drying parameters on drying. Then, a software has been developed using Visual Basic programming language. With the aid of this software, optimum drying conditions for drying time and energy consumption can be obtained for the cotton, viscose, polyester and wool based yarn bobbins.

**Keywords**—Drying, Optimum conditions, Moisture ratio, Visual basic, Yarn bobbins.

## I. INTRODUCTION

THE main objective of any drying process is to produce a dried product of desired quality at minimum cost and maximum throughput and to optimize these factors consistently [1, 2]. Bobbins are passed through several processes such as dyeing and drying before they become market-ready-products. The purpose of drying is to remove the water inside the bobbins. Part of the water in the bobbins is removed mechanically. But this mechanical process is not sufficient to remove water entirely. Therefore, a pressurized convective air dryer is generally used after this process.

Drying is a time consuming, energy intensive and expensive process and constitutes one of the major cost elements among the finishing operations in textile industry. Therefore it is very important to determine optimum drying conditions and accordingly to develop automatic control systems, drying algorithms and software in such systems. For example in a study performed by Yankov and Deliiski (2007), a programmable control system for the convective drying of

lumber in chambers is developed, based on specially designed drying algorithm [3]. In another study, technical considerations for design and construction of the experimental model for an automatic microwave drying system for construction materials have been presented [4].

In this study, a software has been developed to obtain optimum drying conditions for viscose, wool, polyester and cotton based yarn bobbins. For this purpose, firstly, a suitable drying model has been found in defining the drying behavior of bobbins using the experimental drying behavior. After that, further regression analyses have been performed to obtain drying time and energy consumption equations depending on the drying parameters. The developed software specifies the optimum drying conditions using these equations.

## II. MATERIAL AND METHOD

A PLC controlled pressurized hot-air bobbin dryer was used to obtain the drying behavior of viscose, wool, polyester and cotton based yarn bobbins. The schematic view of the experimental setup is shown in Fig. 1.

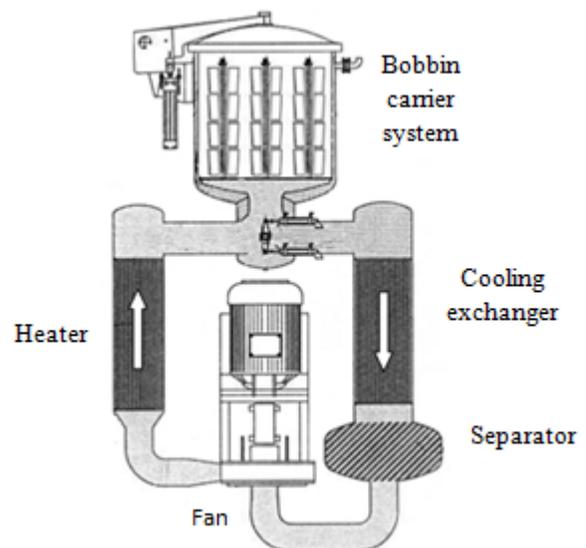

Fig. 1 schematic view of the experimental bobbin dryer

U. Akyol is with the Mechanical Engineering Department, Çorlu Faculty of Engineering, Namik Kemal University, Çorlu, Tekirdag, Turkey (phone: 0090-282-6529475; fax: 0090-282-6529372; e-mail: uakyol@nku.edu.tr).

Ambient air is directed to an electrical heater by a centrifugal fan. Pressurization is realized by a compressor. After the heater, air enters to a bobbin carrier system where the bobbins are dried. The carrier consists of four parts and four bobbins can be placed at each part. In the carrier, hot air is passed repeatedly 10 minutes from inside to the outside of bobbins and 10 minutes from outside to the inside of the bobbins in radial direction. After the carrier, drying air enters to a cooling exchanger and relative humidity of drying air is reduced. Next, drying air enters to a separator. In the separator, water droplets hanging on the air are separated from the air. Drying air finally returns to the fan. The carrier has been placed on a load cell. The conditions of air at different locations in the carrier and weights of the bobbins can be monitored by a software program, and the process can be controlled by an automatic control system.

Drying air is heated in a heating exchanger (Fig. 2) consisting of 10 electrical resistances of 2.5 kW power. The control of heating power is realized by a solid state relay adjusting the phase difference of sinusoidal wave. Heaters are PID (Proportion Integral Derivate) controlled and temperature adjustment is carried out according to this algorithm. Feedback control is provided using a Cu-Ni thermocouple. Four double-acting pneumatic pistons (Fig. 3) with magnetic sensors are used to open, to close, and to secure the lid of bobbin carrier and to control the air redirecting valve. The pistons are driven by pressurized air of 4 bar with the control of valves by outputs of PLC relays.

Relative humidity of the drying air at various locations is conveyed to the PLC after measuring it by a sensor of 4-20mA output and  $0.1 \text{ g/m}^3$  accuracy. Hot air leaving the bobbin carrier is cooled by a cooling exchanger of  $3.89\text{m}^2$  surface area and 35kW cooling power (Fig. 4). After the cooling exchanger, drying air enters to a separator (Fig. 5) and excess moisture is separated from the drying air.

Fig. 3a pneumatic pistons

Fig. 3b pneumatic pistons

Fig. 2 heating exchanger

Fig. 4 cooling exchanger

Fig. 5 separator

An analogue loadcell (Fig. 6) with a 600kg capacity has been used to measure the weight of the bobbins during the drying period. The loadcells are under the bobbin carrier and have 3 load cells.

Fig. 6 loadcell

Analogue thermocouples of 3-4mm diameter, 10mm length and 4-20A (10 - 350  $\Omega$ ) output (Fig. 7) are used to measure the temperature of the drying air at various location of the experimental setup. The temperature at output of separator has been measured with a PT 100 temperature sensor (Fig. 8).

Fig. 7 thermocouples

Fig. 8 PT100 sensors

An analogue pressure sensor of 0.5% accuracy and 0-5bar capacity (Fig. 9e) is conveyed to the PLC using the analogue input of the PLC.

Fig. 9 pressure sensor

A casting-bodied, electromagnetic type, analogue volumetric flow meter of 4-20mA output (Fig. 10) is used to measure the volumetric flow rate of the drying air.

Fig. 10 flow meter

Control of the drying system is provided by a Siemens S7-200 PLC (Fig. 11). By the Ladder diagram of controlling software, drying conditions are observed and controlled on a touch-operated screen.

Fig. 11 control panel

The experimental study is carried out for various values of four different drying parameters: temperature, pressure, volumetric flow rate, and bobbin outer diameter. The moisture ratio of the bobbins and energy consumption during drying are monitored during drying.

III. PROBLEM FORMULATION

Four different empirical or semi empirical drying models given in Table 1 are taken into account to determine the most appropriate model for drying simulation of viscose, wool, polyester and cotton based yarn bobbins.

Table 1 drying models

Name	Model equation	Ref.
Page	$mr = \exp(-kt^n)$	[5]
Henderson and Pabis	$mr = a \exp(-kt)$	[6]
Geometric	$mr = at^{-n}$	[7]
Wang and Singh	$mr = 1 + at + bt^2$	[8]

mr in the drying models is the moisture ratio defined as:

$$mr = \frac{m - m_e}{m_o - m_e} \tag{1}$$

Here m, m<sub>o</sub>, m<sub>e</sub> are the instantaneous, initial and equilibrium moisture contents, respectively.

IV. PROBLEM SOLUTION

Schematic view and geometrical dimensions for the bobbins used in the experiments are shown in Fig. 12 and Table 2 respectively. The experimental results were obtained for drying temperature of 70°C, 80°C, and 90°C, for effective drying pressure of 1bar and 2bar, for volumetric flow rate of 42.5m<sup>3</sup>/h, 55.0m<sup>3</sup>/h, and 67.5m<sup>3</sup>/h per bobbin. Curve fitting computations were carried on the four drying models given in Table 1 relating the drying time and moisture ratio. The results

show that the most appropriate model in describing the drying curves of viscose, wool, polyester and cotton based yarn bobbins is the Page model. After obtaining the coefficients of the Page model, additional regression analyses have been carried out to obtain equations for drying time and energy consumption depending on the drying parameters.

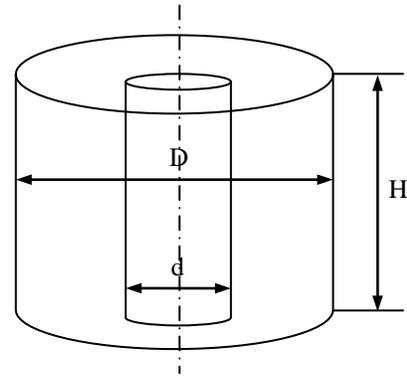

Fig. 12 bobbin geometry.

Table 2 dimensions of the bobbins

H (cm)	d (cm)	D (cm)
15.5	5.4	10
		14
		18

Moisture ratio mr is calculated by the following equation:

$$mr = \exp(-kt^n) \tag{2}$$

Drying time t can be calculated by the following equation:

$$t = \left[ -\ln(mr) / k \right]^{1/n} \tag{3}$$

Here, values of k and n are calculated by the equations 4 and 5 respectively:

$$k = a_1D + a_2Q + a_3P + a_4T + a_5DQ + a_6DP + a_7DT + a_8QP + a_9QT + a_{10}PT + a_{11} \tag{4}$$

$$n = b_1D + b_2Q + b_3P + b_4T + b_5DQ + b_6DP + b_7DT + b_8QP + b_9QT + b_{10}PT + b_{11} \tag{5}$$

The coefficients in equations 4 and 5 depending on the type of yarn as a result of the data obtained from experiments in such a way that the most appropriate value given in the table 3 and 4 respectively.

V. RESULTS AND DISCUSSION

Table 3 values of the coefficients a depending on yarn types

Equation 6 was used to calculate the energy consumption:

$$E = c_1D + c_2Q + c_3P + c_4T + c_5DQ + c_6DP + c_7DT + c_8QP + c_9QT + c_{10}PT + c_{11} \quad (6)$$

The coefficients used in equation 6, obtained from experimental data are determined to provide the most appropriate value given in Table 5.

Using the equations for drying time and energy consumption, a software was developed using the Visual Basic programming language. With the aid of this software, optimum drying conditions for drying time and energy consumption can be obtained. The main window of the developed software is shown in Fig. 13.

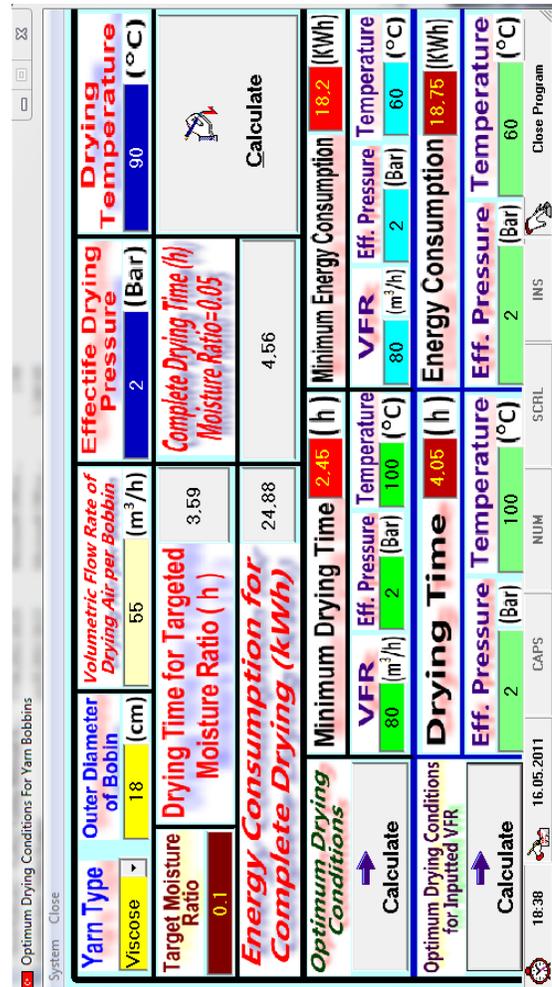

Fig. 13 main window of the developed software

As shown in Fig. 12, software has three sections. In the uppermost first section, there are boxes to input the values of parameters: outer diameter of bobbins, volumetric flow rate of the drying air per bobbin, effective drying pressure and drying temperature. See Fig. 14.

Fig. 14 first section of the software

If the calculate button is pressed, drying time and energy consumption are calculated by the software for the inputted values of the parameters, as you have seen in figure 15.

Target Moisture Ratio <b>0.1</b>	Drying Time for Targeted Moisture Ratio (h) <b>2.40</b>	Complete Drying Time (h) Moisture Ratio=0.05 <b>3.18</b>	
Energy Consumption for Complete Drying (kWh) <b>17.98</b>			

Fig. 15 drying time and energy consumption

In the middle second section, optimum conditions for drying time and energy consumption is shown on the screen for the inputted outer diameter of bobbin after the calculate button is pressed, as you have seen in figure 16.

<b>Optimum Drying Conditions</b> 	Minimum Drying Time <b>1.63</b> (h)	Minimum Energy Consumption <b>12.64</b> (KWh)
	<b>VFR</b> Eff. Pressure Temperature <b>80</b> (m <sup>3</sup> /h) <b>2</b> (Bar) <b>100</b> (°C)	<b>VFR</b> Eff. Pressure Temperature <b>80</b> (m <sup>3</sup> /h) <b>2</b> (Bar) <b>60</b> (°C)

Fig. 16 optimum conditions for drying time and energy consumption

In the undermost third section, optimum conditions for drying time and energy consumption is shown on the screen for the inputted outer diameter of bobbin and volumetric flow rate of drying air per bobbin after the calculate button is pressed, as you have seen in figure 17.

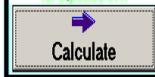

<b>Optimum Drying Conditions for Inputted VFR</b> 	Drying Time <b>2.72</b> (h)	Energy Consumption <b>13.69</b> (KWh)
	<b>Eff. Pressure Temperature</b> <b>2</b> (Bar) <b>100</b> (°C)	<b>Eff. Pressure Temperature</b> <b>2</b> (Bar) <b>60</b> (°C)

Fig. 17 optimum drying conditions for inputted VFR

In the code developed, the coefficients including in the equations for drying time and energy consumption are assigned to the elements of a matrix as shown in Figs. 18a-d. The calculation procedure of optimum drying conditions is shown in Fig. 19.
