Abstract—This paper discusses the application of local interpolation splines of the second order of approximation for the numerical solution of Volterra integral equations of the second kind. Computational schemes based on the use of polynomial and non-polynomial splines are constructed. The advantages of the proposed method include the ability to calculate the integrals which are present in the computational methods. The application of splines to the solution of nonlinear Volterra integral equations is also discussed. The results of numerical experiments are presented.

Keywords—Systems Theory, Dynamical Systems, non-polynomial splines, polynomial splines, Volterra integral equations of the second kind

I. INTRODUCTION

VARIOUS numerical methods are known for solving Volterra integral equations of the second kind. The most common numerical methods are based on the use of quadrature formulas [1]-[3]. New methods for calculating integrals appear periodically. For example, in paper [4] the application of the finite-difference methods are investigated to compute the definite integrals. When solving a variety of tasks, splines are successfully used. Paper [5] deals with the use of the first two vanishing moments for constructing cubic spline-wavelets orthogonal to polynomials of the first degree. The method proposed in [6] can be used to calculate the real eigenvalues of an arbitrary matrix with real elements. This method uses splines of the Lagrangian type of the fifth order and/or polynomial integro-differential splines of the fifth order. In paper [7] periodic cubic splines were used to obtain smooth walking trajectories of every joint in the biped model. Recently, a number of studies have appeared on the use of splines for solving integral equations. Among them, special mention should be made of works using nonpolynomial splines. The most commonly used are polynomial splines.

Non-polynomial splines are used much less often but they can provide a solution with smaller error. Among the studies using splines to solve the problem of solving Volterra integral equation, we note the following. In paper [8] spline functions were used to propose a new scheme for solving the linear Volterra–Fredholm integral equations of the second kind. In paper [10] two types of non-polynomial spline functions (linear, and quadratic) were used to find the approximate solution of Volterra integro–differential equations. In [11], a computational method for solving nonlinear Volterra-Fredholm Hammerstein integral equations is proposed by using compactly supported semiorthogonal cubic B-spline wavelets as basis functions. In [12], the non-polynomial spline basis and Quasi-linearization method to solve the nonlinear Volterra integral equation were used. In [13], a new collocation technique for the numerical solution of the Fredholm, Volterra and mixed Volterra-Fredholm integral equations of the second kind is introduced, and a numerical integration formula on the basis of the linear Legendre multi-wavelets is also developed. In paper [9] the advanced multistep hybrid methods were used for the construction of the numerical methods for solving the Volterra integral equations.

This paper discusses the application of the local interpolation of both polynomial splines and non-polynomial splines (see [14]-[17]) of the second and the third order of approximation for the numerical solution of the Volterra integral equations of the second kind. These splines have the following properties:
- these splines are continuous, piecewise defined functions;
- the support of the basic spline occupies several neighboring grid intervals (the support of the piecewise-linear basic spline occupies two adjacent grid intervals, the support of the piecewise-quadratic basic spline occupies three adjacent grid intervals);
- the approximation is constructed separately on each grid interval in the form of the sum of the products of the values of the function at the grid nodes and the basis splines.
The calculations can be carried out according to the following scheme:

\[ \bar{u}(x_k) = \frac{1}{1 - \frac{hK_{kk}}{2}} \left( \frac{hK_{k0}u(x_0)}{2} + f(x_k) + h \sum_{j=1}^{k-1} K_{kj} \bar{u}(x_j) \right). \]

As a result, we obtain approximate values \( \bar{u}(x_k) \) of the solution \( u \) of integral equation (1) at the grid points.

II. APPLICATION OF SPLINES OF THE SECOND ORDER OF APPROXIMATION

Let us consider the numerical solution of the Volterra equation of the second kind

\[ u(x) + \int_a^x K(x,s)u(s)ds = f(x), \ x, s \in [a, b] \]

using splines of the second order of approximation. Suppose \( K(x,r)u(r) \in C^2[a,b] \). Suppose that \( \{x_j\} \) is a grid of nodes with step \( h \) on the interval \([a, b]\).

The function \( u(s) \) can be approximated by the polynomial spline (see [17])

\[ U(s) = u(x_j)\omega_j(s) + u(x_{j+1})\omega_{j+1}(s), \]

where the basis splines have the form:

\[ \omega_j(s) = \frac{s - x_j}{x_{j+1} - x_j}, \ s \in [x_j, x_{j+1}], \]

\[ \omega_{j+1}(s) = \frac{x_{j+1} - s}{x_{j+1} - x_j}, \ s \in [x_j, x_{j+1}]. \]

Let us denote

\[ \| u'' \|_{[x_j, x_{j+1}]} = \max_{[x_j, x_{j+1}]} |u''(x)|, \]

**Theorem 1.** Let \( u \in C^2[a,b] \). To approximate the function \( u(x), x \in [x_j, x_{j+1}], u \in C^2[a,b] \), by spline (2), the following inequality is valid:

\[ |u(x) - U(x)| \leq K_1 h^2 \| u'' \|_{[x_j, x_{j+1}]}, K_1 = 1/8. \]

**Proof.** It is easy to notice that \( U \) is an interpolation polynomial of the first degree, and \( x_j, x_{j+1} \) are the interpolation nodes,

\[ u(x_j) = U(x_j), \ u(x_{j+1}) = U(x_{j+1}). \]

Using the remainder term we get \( u(x) - U(x) = u''(t)(x - x_j)(x - x_{j+1}), \ t \in [x_j, x_{j+1}]. \)

When \( x \in [x_j, x_{j+1}] \) we can use the relation \( x = x_j + th, t \in [0,1] \). Therefore \( (x - x_j)(x - x_{j+1}) = h^2(t - 1). \)

We can see that \( \max_{t \in [0,1]} |h(t - 1)| = 1/4. \)

Thus \( \max_{x \in [x_j, x_{j+1}]} |u(x) - U(x)| = \max_{[x_j, x_{j+1}]} |u''| h^2/8. \)

The proof is complete.

The function \( u(x), u \in C^2[a,b] \) can also be approximated with non-polynomial splines. As it is shown in paper [17], if the functions \( \varphi_1, \varphi_2 \) form a Chebyshev system, then the basis functions \( \omega_k, k = j, j + 1 \), can be determined by solving the system of equations

\[ \varphi_t(x_j)\omega_t(x) + \varphi_t(x_{j+1})\omega_{j+1}(x) = \varphi_1(x), \]

\[ \varphi_2(x_j)\omega_j(x) + \varphi_2(x_{j+1})\omega_{j+1}(x) = \varphi_2(x), \]

\( x \in [x_j, x_{j+1}] \).

Suppose that the determinant of the system does not equal zero. Let us investigate the case when \( \varphi_t(x) = 1, \varphi_2(x) = \varphi(x). \)

We construct a non-polynomial approximation of function \( u(x) \), on each grid interval \([x_j, x_{j+1}]\) in the form:

\[ U(x) = u(x_j)\omega_j(x) + u(x_{j+1})\omega_{j+1}(x), \]

\( x \in [x_j, x_{j+1}], \)

where

\[ \omega_j(x) = \frac{\varphi(x) - \varphi(x_{j+1})}{\varphi(x_j) - \varphi(x_{j+1})}. \]
Proof. In the case of the polynomial splines as it was shown in paper [17] we construct a homogeneous equation, which has a fundamental system of solutions, \( \phi(x) \)

\[
\omega_{j+1}(x) = \frac{\phi(x) - \phi(x_j)}{\phi(x_{j+1}) - \phi(x_j)}.
\]

Note that this formula for function interpolation can also be applied on a uniform grid of nodes.

Depending on the choice of the function \( \phi(x) \), we obtain slightly different estimates of the error (see paper [17]), but they all have an approximation error of the order of \( O(h^2) \).

This approximation error can be obtained using Taylor’s theorem. But we will apply the method described in paper [17].

Table 1 shows the actual errors of approximation of some functions \( u(x) \) obtained with the use of the polynomial and non-polynomial splines when \( h = 0.1, [a, b] = [-1,1] \).

Let ordered distinct nodes \( \{x_j\} \) be such that \( x_{j+1} - x_j = h \).

**Theorem 2.** Let function \( u(x) \) be such that \( u \in C^2([a, b]) \).

Suppose the basic splines \( \omega_j(x), \omega_{j+1}(x) \) are constructed when \( U(x) = u(x), u(x) = 1, \phi(x) \), for \( x \in [x_j, x_{j+1}] \).

Then, for \( \phi(x) = \exp(x) \), \( \exp(-x) \), \( x \in [x_j, x_{j+1}] \) we have

\[
|u(x) - U(x)| \leq K_2 h^2 \|L u\|, x \in [x_j, x_{j+1}], K_2 > 0.
\]

Here \( L u = \exp(-x) (u''(x) + u'(x)) \) in the case of \( \phi_1(x) = 1, \phi_2(x) = \exp(-x) \),

\( L u = \exp(x) (u''(x) - u'(x)) \) in the case of \( \phi_1(x) = 1, \phi_2(x) = \exp(x) \).

**Proof.** In the case of the non-polynomial splines as it was shown in paper [17] we construct a homogeneous equation, which has a fundamental system of solutions \( 1, \phi(x) \)

\[
L u = \begin{pmatrix} 1 & \phi(x) & u(x) \\ 0 & \phi'(x) & u'(x) \\ 0 & \phi''(x) & u''(x) \end{pmatrix} = 0.
\]

It is easy to see, that the Wronskian \( W(x) = \begin{vmatrix} 1 & \phi(x) \\ 0 & \phi'(x) \end{vmatrix} \) does not equal zero when \( \phi(x) = \exp(x) \), or \( \exp(-x) \). Now we can construct a general solution of the nonhomogeneous equation \( L u = F \) by the method of variation of the constants.

Expanding the determinant according to the elements of the last column and dividing all terms of the equation by \( W(x) \) we obtain the equation \( L u = 0 \) in the form. \( u'' + q u' + p u = 0 \). Here \( q \) and \( p \) are some coefficients.

After we have constructed a general solution of nonhomogeneous equation \( L u = F \) by the method of variation of the constants we obtain the function \( u(x), x \in [x_j, x_{j+1}] \).

Let us write down the results for several special cases.

In the case of \( \phi_1(x) = 1, \phi_2(x) = \exp(x) \) we obtain

\[
u(x) = \int_{x_j}^{x} \exp(t) (u''(t) - u'(t)) dt + c_1 + c_2 \exp(x).
\]

In the case of \( \phi_1(x) = 1, \phi_2(x) = \exp(-x) \) we obtain

\[
u(x) = -\int_{x_j}^{x} (u''(t) + u'(t)) \exp(-t) dt + c_1 + c_2 \exp(-x).
\]

Here \( c_1, i = 1, 2, \) are some arbitrary constants, \( x \in [x_j, x_{j+1}] \).

We construct the approximation of \( u(x) \) in the form:

\[
U(x) = u(x_j) \omega_j(x) + u(x_{j+1}) \omega_{j+1}(x), x \in [x_j, x_{j+1}].
\]

Thus, using the results from paper [17], we get

\[
|u(x) - U(x)| \leq K_2 h^2 \|L u\|, x \in [x_j, x_{j+1}],
\]

in the case of \( \phi_1(x) = 1, \phi_2(x) = \phi(x) \).

The proof is complete.

Now we will consider, in detail, the construction of computational schemes for solving the Volterra equation of the second kind. In the construction of the computational schemes, we will use the approximation formulas with polynomial and non-polynomial splines of the second order of approximation.

Transforming the integral \( \int_{x_j}^{x_{j+1}} K(x, s) u(s) ds \) using formula (2) or (1), we obtain

\[
\int_{x_j}^{x_{j+1}} K(x, s) u(s) ds = u(x_j) \int_{x_j}^{x_{j+1}} K(x, s) \omega_j(s) ds + u(x_{j+1}) \int_{x_j}^{x_{j+1}} K(x, s) \omega_{j+1}(s) ds + O(h^2).
\]

To construct a numerical method, we discard the error and denote \( \tilde{u}(x_j) \approx u(x_j) \). Let us introduce the notation

\[
W_j(x) = \tilde{u}(x_j) \int_{x_j}^{x_{j+1}} K(x, s) \omega_j(s) ds + \tilde{u}(x_{j+1}) \int_{x_j}^{x_{j+1}} K(x, s) \omega_{j+1}(s) ds.
\]

Setting \( x = x_k \), we obtain the numerical method

\[
\tilde{u}(x_k) + \sum_{k=0}^{n} W_k(x_k) = f(x_k), \quad k = 0, ..., n.
\]

In a more detailed notation, the system of equations has the form

\[
\tilde{u}(x_0) = f(x_0),
\]

\[
\tilde{u}(x_1) + \tilde{u}(x_0) \int_{x_0}^{x_1} K(x_1, s) \omega_0(s) ds + \tilde{u}(x_2) \int_{x_1}^{x_2} K(x_2, s) \omega_0(s) ds + \tilde{u}(x_3) \int_{x_2}^{x_3} K(x_3, s) \omega_0(s) ds + ... + \tilde{u}(x_n) \int_{x_{n-1}}^{x_n} K(x_n, s) \omega_0(s) ds = f(x_n).
\]
\[ \sin(x) \sin(1) - \left(2 \cdot 10 \cdot 10 \cdot 10 \cdot 10 \cdot 10 \cdot 10 \cdot 10 \right) = 10 \]

The error obtained with the application of the linear polynomial splines (column 2). The maximum of the error in absolute value obtained with the application of the non-polynomial splines when \( \varphi(x) = \exp(x) \) is given in the column 3. The maximum of the error in absolute value obtained with the application of the composite trapezoidal rule is presented in the fourth column of Table 3. The number of nodes \( n \) is given in the first column of Table 3.

Now let us solve some equations from paper [13] and compare the results with the result obtained with the polynomial and the non-polynomial splines. Let us compare the results with the result obtained with the composite trapezoidal rule.
Problem 2. We take the equation 7 from paper [13].
\[ u(x) = \exp(-x) + x \exp(x) - \int_0^x \exp(x + t)u(t)\,dt, \quad x \in [0, 1]. \]

The exact solution of the equation is \( u(x) = \exp(-x) \).

Fig. 3. The plot of error between the exact solution of the equation (problem 2) and the numerical solution obtained with the application of the linear polynomial splines when we use 128 nodes.

When we use the linear piecewise polynomial splines with the 64 nodes on the interval [0, 1] we receive the plot of the error between the exact solution of the equation and the numerical solution obtained with the application of the linear polynomial splines. This plot is shown in Fig. 3. When we use the non-polynomial splines \( \varphi(x) = \exp(-x) \) with the 64 nodes on the interval [0, 1] we receive the plot of the error between the exact solution of the equation and the numerical solution. This plot is shown in Fig. 4.

When we use the non-polynomial splines \( \varphi(x) = \exp(x) \) with the 128 nodes on the interval [0, 1] we receive the plot of the error between the exact solution of the equation and the numerical solution.

Table 4 shows the maximum of the error in absolute value between the exact solution of the equation (Problem 2) and the numerical solution obtained with the application of the linear polynomial splines (column 2). The maximum of the error in absolute value obtained with the use of the non-polynomial splines \( \varphi(x) = \exp(x) \) is presented in the third column of Table 4. The number of nodes \( n \) is given in the first column of Table 4. The application of the composite trapezoidal rule for this equation gives us the exact solution.

Problem 3. We take the equation
\[ u(x) = g(x) + \int_0^x (1 - (x - s)\exp(x))u(t)\,dt, \quad x \in [0, 1]. \]

Here \( g(x) = 1 - \exp(x) \sin(x) - x \exp(x) - \exp(x)/2 + \exp(2x)(\sin(x) + \cos(x))/2. \)

The exact solution of the equation is \( u(x) = \exp(x)(\cos(x) - \sin(x)). \)

Table 5 shows the maximum of the error in absolute value between the exact solution of the equation (Problem 3) and the numerical solution obtained with the application of the linear polynomial splines (column 2). The maximum of the error in
absolute value obtained with the application of the non-poly-
non-polynomial splines \((\varphi(x) = \exp(x))\) is presented in column 3, the error obtained with the composite trapezoidal rule application is given in the fourth column of Table 5. The number of nodes \((n)\) is given in the first column of Table 5.

The plot of error between the exact solution of the equation (problem 3) and the numerical solution obtained with the application of the exponential splines when we use 128 nodes is given in Fig.7. The plot of error between the exact solution of the equation and the numerical solution obtained with the application of the composite trapezoidal rule when we use 128 nodes is given in Fig.8.

**Fig.7.** The plot of error between the exact solution of the equation (problem 3) and the numerical solution obtained with the application of the exponential splines when we use 128 nodes

**Fig.8.** The plot of error between the exact solution of the equation (problem 3) and the numerical solution obtained with the application of the composite trapezoidal rule when we use 128 nodes

IV. APPLICATION TO SOLVING A NONLINEAR EQUATION

Let us now consider the application of splines of the second order of approximation to the solution of the nonlinear Volterra integral equation of the second kind.

\[
\int_{a}^{b} K(x, s, u(s)) ds = f(x), \quad x \in [a, b].
\]

We approximate \(u(s)\) with the expression:

\[
U(x) = u(x_j) \omega_j(x) + u(x_{j+1}) \omega_{j+1}(x), \quad x \in [x_j, x_{j+1}].
\]

Now transforming the integral \(\int_{x_j}^{x_{j+1}} K(x, s, u(s)) ds\) using formula (3), we obtain

\[
\int_{x_j}^{x_{j+1}} K(x, s, u(s)) ds \approx \int_{x_j}^{x_{j+1}} K(x, s, U(s)) ds.
\]

Here we take the nonlinear Volterra integral equation of the second kind of the form:

\[
\int_{a}^{b} K(x, s, u(s)) ds = f(x), \quad x \in [a, b].
\]

Now let us solve the equation from paper [13] and compare the results with the result obtained with splines. In problem 4 we consider problem 6 from paper [13].

**Problem 4.** We take the equation

\[
u(x) = g(x) + \int_{0}^{x} x s^2 u^2(s) ds, \quad x \in [0, 1].
\]

Here

\[
g(x) = (1 + 2x^4/9 - x^3/3 + 2x^2/3 + 11x/9)\log(x + 1) + \left(-\frac{x^4}{3} - \frac{x^3}{3}\right)(\ln(x + 1))^2 + 5x^2/18 - 11x^2/9 - 2x^4/27.
\]

The exact solution is taken by \(u(x) = \log(x + 1)\).

When we use the linear piecewise polynomial splines with the 128 nodes on the interval [0,1] we receive the plot of the error between the exact solution of the equation and the numerical solution obtained with the application of the linear polynomial splines which is shown in Fig.9.

**Fig.9.** The plot of error between the exact solution of the equation (problem 4) and the numerical solution obtained with the application of the linear polynomial splines when we use 128 nodes

Table 6 shows the maximum of the error in absolute value between the exact solution of the equation (Problem 4) and the numerical solution obtained with the application of the linear polynomial splines (column 2). The maximum of the error in absolute value obtained with the application of the non-polynomial splines \((\varphi(x) = \exp(x))\) is presented in column 3. The maximum of the error in absolute value obtained with the application of the non-polynomial splines \((\varphi(x) = \exp(-x))\) is given in column 4. The number of nodes \((n)\) is given in the first column of Table 6.
When we use the piecewise non-polynomial splines with the 128 nodes on the interval \([0,1]\) we receive the plots of the error between the exact solution of the equation and the numerical solution obtained with the application of the non-polynomial splines which are shown in Figs. 10-11.

Comment. This paper considers the case when it is possible to calculate the exact integral of the product of the kernel and the basis function. If this is not possible, then we can use a quadrature formula, for example, Simpson’s rule.

We construct the function \(g(x)\) by specifying the piecewise function \(u(x)\) (see Fig.12). The plot of the solution of Volterra integral equation of second kind obtained with the application of the linear polynomial splines when 64 nodes were taken is given in Fig.12.

The plot of error between the exact solution of the equation solution obtained with the application of the linear polynomial splines when 64 nodes were taken is given in Fig.14.

Now let us take the next model problem

\[
u(x) = g(x) + \int_0^x (t + xt^2)u(t)\,dt, \quad x \in [0,1]
\]

We construct the function \(g(x)\) by specifying the piecewise function \(u(x)\) (see Fig.15). The plot of the solution \(u(x)\) is similar to the plot from paper [18]. The plot of the solution of Volterra integral equation of second kind obtained with the application of the linear polynomial splines when 128 nodes were taken is given in Fig.16. The plot of error between the exact solution of the equation solution obtained with the application of the linear polynomial splines when 128 nodes were taken is given in Fig.17. Our method can find applications in [19] and [20].
V. CONCLUSION

In this paper, polynomial and non-polynomial splines of the second order of approximation are used to solve the linear and nonlinear models of the Volterra integral equations of the second kind. It is assumed, that the integral of the product of the kernel and the basis spline can be calculated exactly (in the form of a formula). The basis spline is the polynomial spline or non-polynomial spline of the second order of approximation. The numerical examples are done. The graphs of the error between the exact and approximate solutions at the different number of grid points are also drawn. As it is shown, the application of the local interpolation splines of the second order of approximation for the Volterra integral equations of the second kind can give an appropriate result, better than the composite trapezoidal rule. The non-polynomial splines sometimes can provide the result better than the polynomial splines. The application of the presented method to solve the model of an engineering problem presented in paper [18] gave a completely reliable result.
